Multispecies justice
Evidence and decision-support limits

> **Chosen region:** Sierra de la Culebra, Zamora, Castilla y León, Spain.
> **Case:** June 2022 wildfire.

"**-**" means that ANWE currently lacks sufficient site-specific evidence. Its AI can propose hypotheses and field checks, but those are not validated ecological predictions.

Inputs

Question	Current answer
Which animals currently use the burned area?	-
Which species require open post-fire habitat?	-
Which species require cover to avoid predation?	-
Where are surviving refuges?	-
Which corridors connect unburned habitat?	-
Does rapid planting remove habitat that some species now use?	-
Does an intervention disturb breeding periods?	-
How strong is the evidence?	Official CEMS mapping supports the documented fire extent at its observation date. Sentinel-2 provides imagery and, after successful processing, derived vegetation indices. GBIF provides historical regional observations. Evidence is insufficient to establish current occupancy, animal welfare, habitat requirements or intervention effects.

Outputs

Requested output	What ANWE can currently provide
Restoration actions and sequence	Three conditional options for comparison: passive recovery, assisted natural regeneration and active intervention. A validated site-specific action sequence: -
Spatial areas affected	The mapped CEMS burned extent and regional analysis window. Locations where particular interventions should occur: -
Habitat functions being restored	-
Animal groups expected to benefit	-
Animal groups potentially disadvantaged	-
Supporting ecological evidence	CEMS mapped burned extent; Sentinel-2 acquisition metadata and imagery; calculated NDVI/NBR/dNBR when processing succeeds; historical GBIF observations with provenance.
Confidence/uncertainty	Source dates, methods and limitations are documented. Quantified confidence in restoration outcomes: -
Actions requiring field verification	Any proposed intervention requires checks of current animal use, habitat requirements, refuges, connectivity, breeding activity and potential disturbance before implementation.
Monitoring indicators	Proposed indicators include repeated vegetation-index measurements, animal presence and habitat-use surveys, breeding activity, refuge condition and corridor use. Site-specific baselines, targets and validated protocols: -

Multispecies justice limitation

Mapping vegetation recovery does not establish whether restoration benefits individual animals or distributes harms fairly across species. ANWE helps make those questions explicit; answering them requires additional ecological and field evidence.
